Robust Reinforcement Learning under Sticky Actuators

Tabular Q-learning vs SARSA on a modified MountainCar-v0

Deep Reinforcement Learning: Assignment II (Set A, Group 1-100) · **Group 84** · File: *Group 84 - Q_learning_SARSA_Set A*

Group Contribution Declaration

#	Name	Registration No.	Email	Contribution
1	SHREYANSH SHARMA	2025AG05772	2025ag05772@wilp.bits-pilani.ac.in	**100%**
2	LAKSHYA KANCHAN	2025AG05062	2025ag05062@wilp.bits-pilani.ac.in	**100%**
3	VINAY PRATAP SINGH BHADAURIA	2025AG05689	2025ag05689@wilp.bits-pilani.ac.in	**100%**

All three members contributed equally to the design, implementation, experiments and the write-up.

How this report is organised

Section	Content	Marks
0	Setup: execution environment, configuration, helpers	n/a
(a)	Sticky-actuator wrapper and its experimental verification	2
(b)	Discretization, Q-learning agent, training on both environments	3
(c)	SARSA agent (only the TD target differs), training on both environments	3
(d)	Performance evaluation: 5 plot families, policy maps, greedy test table	3
(e)	Discussion: 5 questions answered with our measurements	2
(f)	Virtual-lab execution screenshots (with timestamps)	n/a
App. A-C	Hyper-parameter pilot, complete per-episode logs (every iteration)	n/a

What we built. The whole solution is written by hand in NumPy as a small package, `drl_sticky`. It contains the wrapper, discretizer, agents, training loop, evaluation and plots. Every module is reproduced in full below through `%%writefile` cells. Running this notebook top to bottom writes the package, runs every experiment and regenerates every number and figure in this PDF. Gymnasium supplies only the MountainCar-v0 physics. No RL library is used.

Reproducibility. We use one master seed, **84** (our group number). Separate RNG streams are derived from it for (i) environment resets, (ii) the sticky actuator and (iii) the agent's exploration. Because the streams are separate, the actuator noise never shifts the agent's exploration draws. The four required agents share exactly the same `Config` object.

0. Setup and execution environment

The first cell records **when and where** this notebook was executed (time stamp, host name, library versions). In the virtual-lab run this output is the execution evidence that complements the screenshots in Section (f).

Configuration shared by all four agents

Parameter	Value	
Discretization	20 x 20 uniform bins (position width 0.090, velocity width 0.0070)	at least 20x20 required. A held-out-se
Q-table	shape (20, 20, 3), initialised to 0	Required by the spec. Every step rewa
Learning rate alpha	0.1	best of 0.05 / 0.1 / 0.2 in the pilot
Discount gamma	0.99	200-step horizon; the +20 bonus mus
Exploration	epsilon_k = max(0.01, 1.0 * 0.999342^k), k = episode	exponential decay reaching the floor a
Episodes	10000 per agent	at least 5000 required; the pilot show
Seeds	master 84; derived streams {'env_reset': 84, 'sticky': 1084, 'agent': 2084, 'validation': 3084}	identical for all four runs

(a) Modified Environment Implementation and Verification

a.1 Implementation

`StickyActuatorMountainCar` (in `drl_sticky/env.py`, listed below) subclasses **`gym.Wrapper`** and performs Steps 1-6 **in the prescribed order**:

1. **Receive** the selected action `a` and keep it for the reward.
2. **Sticky actuator.** If `a == a_prev` the action runs unchanged, and *no random number is drawn*. Otherwise draw `r ~ U[0,1)`. If `r < 0.20` the action is replaced by `a_prev`, otherwise `a` is kept. Then set `a_prev = a_exec`.
3. **Execute** `a_exec` in the original MountainCar-v0 and receive `obs, R_base, terminated, truncated, info`.
4. **Modified reward:** `R = R_base - 0.2 * 1[a != 1] + B`, using the **selected** action `a`.
5. **Gentle-arrival bonus:** `B = +20` iff `terminated and not truncated and obs[0] >= 0.5 and obs[1] <= 0.04`.
6. **Return** `obs, R, terminated, truncated, info`. The `info` dict is the base environment's own dict, untouched.

`reset()` sets `a_prev = 1`. The sticky RNG belongs to the wrapper. The attributes starting with `last_` exist only for the audit below. They never appear in the observation or in `info`, so the agent gets no hint that an action was replaced.

```
%%writefile drl_sticky/env.py
"""Sticky-actuator MountainCar-v0 wrapper (task a).

The wrapper changes ONLY two things of the base environment:
```

```
  1. action execution  - an attempted action change is ignored with prob. 0.20;
  2. the reward        - energy penalty on the *selected* push + gentle-arrival bonus.
Observation space, action space, dynamics, termination/truncation and the info
dictionary are passed through untouched.
"""

    """gym.Wrapper implementing Steps 1-6 of the assignment's Environment Modifications.

    Hidden internal state: ``a_prev`` = the action actually executed on the previous
    step (reset to 1 on every ``reset``). It is never exposed to the agent.

    Diagnostic attributes whose names start with ``last_``/``n_`` exist only so the
    verification experiments of task (a) can audit the wrapper; they are NOT part
    of the observation or of ``info``, so the learning agents never see them.
    """

```
Overwriting drl_sticky/verify.py
```

a.2 Components that must remain unchanged

```
# Run the complete verification suite of task (a) (random policy: 2000 episodes = 400k steps)
from drl_sticky import verify
t0 = time.time()
R["verification"] = {"spec": verify.spec_compliance(), "pdf_example": verify.replay_pdf_example(),
                     "random_audit": verify.random_policy_audit(2000), "bonus_audit": verify.bonus_audit(300),
                     "non_markov": verify.non_markov_evidence(1500)}
print(f"verification finished in {time.time()-t0:.1f}s")
```

```
spec = R["verification"]["spec"]
pd.DataFrame({"check": list(spec.keys()), "result": [str(v) for v in spec.values()]})
```

```
verification finished in 5.2s
```

	check	result
0	observation_space_equal	True
1	action_space_equal	True
2	max_episode_steps	200
3	dynamics_identical_when_not_stuck	True
4	termination_truncation_identical	True
5	info_identical_keys	True
6	info_keys_sticky_env	[]
7	base_reward_minus_one	True
8	a_prev_after_reset	1

Same seed and same action sequence, with stick probability set to 0, give **bit-identical observations and identical terminated/truncated flags** to the base environment. So the dynamics, termination (flag at 0.5) and truncation (200 steps) are untouched. The observation and action spaces are equal to the originals. `info` has exactly the base keys `[]`, and `a_prev` is `1` right after `reset()`.

a.3 The assignment's worked example (scripted random numbers 0.55, 0.11, 0.74, 0.05)

```
# Replay the 5-step example table of the assignment with a scripted RNG
pd.DataFrame(R["verification"]["pdf_example"]).set_index("step")
```

step	a_prev	a	r	a_exec
1	1	2	0.55	2
2	2	2	-	2
3	2	0	0.11	2
4	2	0	0.74	0
5	0	1	0.05	0

The executed actions are **2, 2, 2, 0, 0**, exactly as in the assignment's table. At step 2 no number is drawn because the agent repeats the executed action. At step 5 the change 0 to 1 is blocked because 0.05 < 0.20.

a.4 About 20% of attempted changes are replaced, and none when the action is repeated

```
# Random-policy audit: counts over every step of 2000 episodes
aud = R["verification"]["random_audit"]
summary = pd.DataFrame([
    ["episodes / steps", f"{aud['episodes']} / {aud['steps']}"],
    ["attempted changes (a != a_prev)", aud["attempted_changes"]],

12	0	0	1	0.515	1	-1.0	0.0	0.0	-1.0
13	0	1	1	-	1	-1.0	0.0	0.0	-1.0
14	0	1	2	0.079	1	-1.0	0.2	0.0	-1.2
15	0	1	0	0.977	0	-1.0	0.2	0.0	-1.2
16	0	0	2	0.959	2	-1.0	0.2	0.0	-1.2
17	0	2	0	0.207	0	-1.0	0.2	0.0	-1.2
18	0	0	0	-	0	-1.0	0.2	0.0	-1.2
19	0	0	2	0.309	2	-1.0	0.2	0.0	-1.2
20	0	2	0	0.045	2	-1.0	0.2	0.0	-1.2
21	0	2	0	0.248	0	-1.0	0.2	0.0	-1.2
22	0	0	0	-	0	-1.0	0.2	0.0	-1.2
23	0	0	1	0.289	1	-1.0	0.0	0.0	-1.0
24	0	1	1	-	1	-1.0	0.0	0.0	-1.0

Out of **266,632** attempted changes, **53,377** were replaced, a rate of **20.02%**. The 95% CI [19.87%, 20.17%] contains 20%. Out of **133,368** steps where the agent repeated the executed action, **0** were modified.

a.5 The energy penalty follows the *selected* action

```
# For every (selected a, executed a_exec) pair: how many steps, and in how many the penalty was exactly
0.2*1[a!=1]
pairs = pd.DataFrame({"steps": aud["pair_counts"], "penalty correct": aud["penalty_correct"]})
pairs["expected penalty"] = [0.2 if not k.startswith("a=1") else 0.0 for k in pairs.index]
pairs["stuck?"] = [k.split(",")[0][2:] != k.split(",")[1][7:] for k in pairs.index]
display(pairs)
print("penalised steps with selected a = 1     :", aud["penalty_on_selected_1"])
print("unpenalised steps with selected a = 0/2 :", aud["penalty_missing_on_push"])
```

	steps	penalty correct	expected penalty	stuck?
a=0,a_exec=0	115215	115215	0.2	False
a=0,a_exec=1	9163	9163	0.2	True
a=0,a_exec=2	8865	8865	0.2	True
a=1,a_exec=0	8729	8729	0.0	True
a=1,a_exec=1	115917	115917	0.0	False
a=1,a_exec=2	8821	8821	0.0	True
a=2,a_exec=0	8758	8758	0.2	True
a=2,a_exec=1	9041	9041	0.2	True
a=2,a_exec=2	115491	115491	0.2	False

```
penalised steps with selected a = 1     : 0
unpenalised steps with selected a = 0/2 : 0
```

The penalty is read back from the returned reward as `R_base + B − R`. Every row has *penalty correct* = *steps*. The off-diagonal rows matter most: **a=0, a_exec=2** and **a=2, a_exec=1** are stuck pushes that are still charged 0.2, and **a=1, a_exec=0/2** means the actuator kept pushing while the agent chose to coast, and it is **not** charged. As the specification requires, the penalty depends only on the selected action.

a.6 The +20 bonus is paid only for a gentle arrival

```
# A random policy almost never reaches the flag, so hand-coded policies are used:
#  - push in the direction of the velocity (often arrives too fast),
#  - the same with braking near the flag (arrives slowly),
```

```
#  - always 'no push' (never arrives -> truncation at 200 steps).
bon = R["verification"]["bonus_audit"]
rows = []
for pol, d in bon["policies"].items():
    for outcome, n in d["counts"].items():
        rows.append([pol, outcome, n, d["arrival_velocity_mean"]])
display(pd.DataFrame(rows, columns=["policy", "outcome | bonus", "episodes", "mean arrival velocity"]))
print("episodes where bonus != 20*[gentle arrival]:", bon["violations"])
pd.DataFrame(bon["examples"])
```

	policy	outcome | bonus	episodes	mean arrival velocity
0	velocity (push with v)	fast arrival | B=0	198	0.041761
1	velocity (push with v)	gentle arrival | B=20	102	0.041761
2	velocity + brake after x>0.0	gentle arrival | B=20	300	0.026404
3	velocity + brake after x>0.3	fast arrival | B=0	122	0.035045
4	velocity + brake after x>0.3	gentle arrival | B=20	178	0.035045
5	always no-push (1)	truncated | B=0	300	NaN

```
episodes where bonus != 20*[gentle arrival]: 0
```

	policy	kind	final_pos	final_vel	terminated	truncated	B	last_R
0	velocity (push with v)	fast arrival	0.5259	0.0410	True	False	0.0	-1.2
1	velocity (push with v)	fast arrival	0.5369	0.0500	True	False	0.0	-1.2
2	velocity (push with v)	gentle arrival	0.5128	0.0332	True	False	20.0	18.8
3	velocity (push with v)	gentle arrival	0.5164	0.0192	True	False	20.0	18.8
4	always no-push (1)	truncated	-0.5206	0.0061	False	True	0.0	-1.0
5	always no-push (1)	truncated	-0.5267	-0.0058	False	True	0.0	-1.0

Every gentle arrival (terminated, not truncated, position >= 0.5, velocity <= 0.04) received **B = 20**. Every fast arrival and every truncation received **B = 0**. There are no violations.

(b) Q-Learning

b.1 State discretization

`UniformDiscretizer` maps (position, velocity) to bin indices, with `idx = clip(floor((x - low)/width), 0, n-1)` applied in each dimension. The **Q-table** has shape *(position bins x velocity bins x 3)* and starts at zero.

b.2 Agent and update rule

`TabularTDAgent` holds the Q-table, the epsilon-greedy policy (ties among equal maxima are broken at random, which matters with a zero-initialised table) and the generic update `Q(s,a) <- Q(s,a) + alpha * (target - Q(s,a))`. `QLearningAgent` overrides only the target:

`target = R + gamma * max_a' Q(s', a')`, or just `R` when the episode is **terminated** (reaching the flag is a true terminal state). On **truncation** at 200 steps the agent still bootstraps, because a time-out is not a terminal state of the task.

Here `a` is the **selected** action. The executed action is hidden from the agent.

b.3 Training loop

The same loop trains both algorithms. The next action `a'` is chosen epsilon-greedily *before* the update and is then actually executed. Q-learning ignores `a'` in its target, and SARSA uses it. As a result **the TD target is the only difference** between the two experiments. The loop logs every episode: return, length, success, gentle arrival, arrival velocity, selected pushes, epsilon, the average predicted value on the validation set, and (for the audit only) the number of sticky replacements.

(c) SARSA

SARSA uses **the same** discretization, zero Q-table, alpha, gamma, epsilon schedule, random seeds and number of episodes, because it receives the same `CFG` object. The class definitions below are printed from `drl_sticky/agents.py`. `SarsaAgent` overrides **only** `td_target`, which bootstraps from `Q(s', a')` where `a'` is the next action the epsilon-greedy policy actually chose:

`Q(s,a) <- Q(s,a) + alpha * [R + gamma * Q(s',a') - Q(s,a)]`, with no bootstrap when terminated.

```
# Show that the two agents differ ONLY in td_target
from drl_sticky.agents import QLearningAgent, SarsaAgent, TabularTDAgent
own = lambda cls: sorted(k for k, v in vars(cls).items() if inspect.isfunction(v))
print("methods defined by QLearningAgent:", own(QLearningAgent))
print("methods defined by SarsaAgent    :", own(SarsaAgent))
print()
print(inspect.getsource(QLearningAgent.td_target))
print(inspect.getsource(SarsaAgent.td_target))
```

```
methods defined by QLearningAgent: ['td_target']
methods defined by SarsaAgent    : ['td_target']
```

```
    def td_target(self, r: float, s_next: State, a_next: int, terminated: bool) -> float:
        """Bootstrap from the greedy value of s' (a_next is ignored); none if terminated."""
        if terminated:                                  # true terminal state: no future value
            return r
        return r + self.gamma * float(self.Q[s_next].max())

    def td_target(self, r: float, s_next: State, a_next: int, terminated: bool) -> float:
        """Bootstrap from the value of the action actually chosen next; none if terminated."""
        if terminated:                                  # true terminal state: no future value
            return r
        return r + self.gamma * float(self.Q[s_next + (a_next,)])
```

```

(d) Performance Evaluation

The four agents are **Q-learning / SARSA x original / modified environment**. In every figure, **colour = algorithm** (blue = Q-learning, orange = SARSA) and **panel = environment**. Thin faint lines show individual episodes and thick lines show the 100-episode trailing moving average.

Note on reward scales. The original environment pays -1 per step. The modified environment pays -1.2 per step when a push is selected, plus 20 for a gentle arrival. Rewards are therefore compared **between algorithms**

within an environment. Across environments we compare success, gentle-arrival rate, episode length and push counts, which share the same units.

Evaluation, plotting and experiment-orchestration code (used from here on):

d.1 Episode reward versus training episode

```
# Plotting helpers, then Fig. d.1: episode reward (raw + 100-episode moving average) per environment
from drl_sticky.plotting import (plot_metric_panels, plot_value_overlay, plot_rates, plot_policy_maps,
                                 plot_arrival_speed, plot_seed_robustness, plot_bins_ablation)
from drl_sticky.discretizer import UniformDiscretizer
plot_metric_panels(LOGS, "return", "Episode reward", "Episode reward vs training episode",
"figures/fig1_reward.png")
Image("figures/fig1_reward.png", width=900)
```

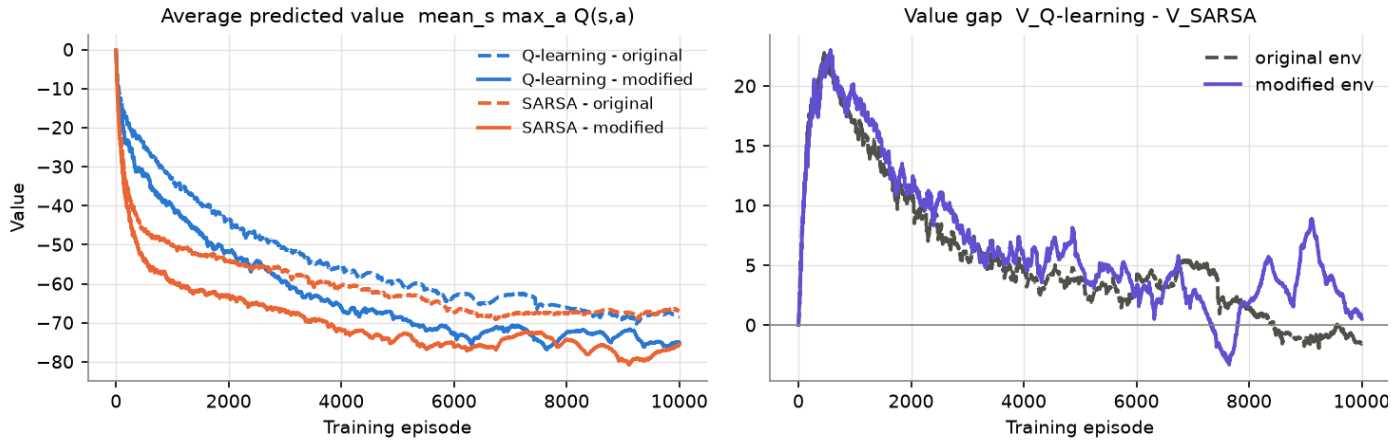

Interpretation. No agent reaches the flag for roughly the first thousand episodes. The first successes come at episode **1089** (Q-learning, original), **1125** (SARSA, original), **1595** (Q-learning, modified) and **1213** (SARSA, modified). Until then the reward is flat at -200 in the original environment. In the modified environment it is about -227, which is -200 minus 0.2 for each of the ~136 pushes an almost random policy selects. Once the flag has been found, the step cost propagates back through the table and the reward climbs as epsilon decays. The epsilon floor is reached at episode 7000.

Q-learning vs SARSA. In the **original** environment the two moving averages overlap for most of training. Over the last 500 episodes they score -156.0 (Q-learning) and -160.8 (SARSA). With epsilon = 0.01 the max-target and the epsilon-greedy target are almost the same. In the **modified** environment the curves are visibly noisier, because the sticky actuator randomly delays action switches and the same policy produces different outcomes. At the end of training SARSA is ahead for this seed: -121.1 (SARSA) vs -173.0 (Q-learning) over the last 500 episodes. Section d.7 shows how much of this depends on the seed.

Original vs modified. The modified reward includes the -0.2 push penalty and the +20 bonus, so the two panels are not on the same scale. The bonus is why the best modified-environment episodes can beat the -1-per-step bound that holds in the original environment.

d.2 Average predicted value mean over validation states of max_a Q(s,a)

```
# Fig. d.2: average max_a Q(s,a) over the fixed validation set, and the Q-learning − SARSA gap
plot_value_overlay(LOGS, "figures/fig2_value.png")
Image("figures/fig2_value.png", width=900)
```

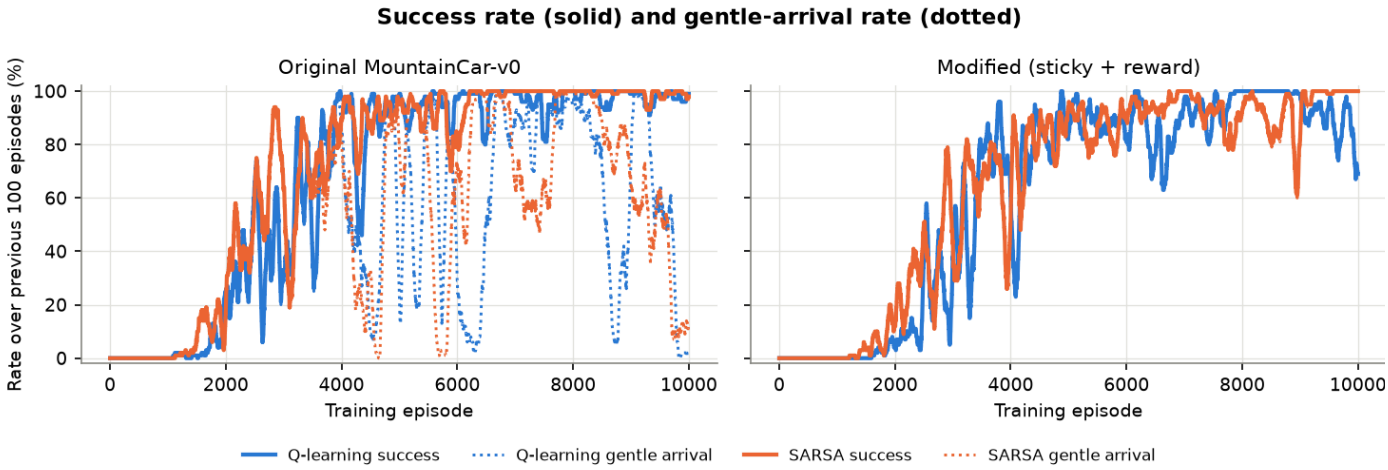

Interpretation. All four curves start at **0**, the optimistic initial value, and fall as the agents learn the real cost-to-go. After the last episode the average predicted values are -68.5 / -66.9 (Q-learning / SARSA, original) and -75.1 / -75.6 (modified). Values in the modified environment are lower for two reasons. A push step costs 1.2 instead of 1. The +20 bonus is earned only at the end of an episode, so when discounted from a typical validation state about 100 steps away it is worth only around 20 * 0.99^100 ≈ 7.

Q-learning vs SARSA. While exploration is high, Q-learning's curve lies clearly **above** SARSA's. Q-learning bootstraps from max_a' Q(s',a'), the value of the greedy continuation. SARSA bootstraps from the action actually taken, and with epsilon close to 1 that is mostly a costly random action. The gap (right panel) peaks at 22.8 (original) and 23.0 (modified) near episode 458/572. It then shrinks as epsilon decays, because the two targets converge. Averaged over the whole of training the gap is **5.70** in the original and **6.94** in the modified environment. In the last 500 episodes it is -0.81 and 1.70. Question (e1) analyses this further.

d.3 Success rate and gentle-arrival rate (moving average over the previous 100 episodes)

```
# Fig. d.3: success and gentle-arrival rates, moving average over the previous 100 episodes
plot_rates(LOGS, "figures/fig3_rates.png")
Image("figures/fig3_rates.png", width=900)
```

Interpretation. Success rates rise from 0% to over 90% between roughly episode 1,500 and episode 4,000. Over the last 500 episodes they are 98.0% / 99.0% (Q-learning / SARSA, original) and 83.2% / 100.0% (modified). The sharp, short drops show how sensitive the greedy part of the policy still is: a few value updates can flip the action in frequently visited cells, and the rate recovers within a few hundred episodes.

Gentle arrivals. In the **original** environment the dotted gentle-arrival curves swing wildly. Nothing in the original reward separates a slow arrival from a fast one, so the arrival speed drifts around the 0.04 threshold: the mean arrival velocity over the last 500 episodes is 0.036 / 0.040. Only 23.0% / 20.4% of the last 500 episodes end gently. In the **modified** environment the dotted curves sit **under the solid ones**: practically every arrival is gentle. Over the last 500 episodes the gentle rate is 83.2% / 100.0% against success of 83.2% / 100.0%. The bonus has taught both agents to control their arrival speed.

d.4 Average number of push actions (0 or 2) selected per episode

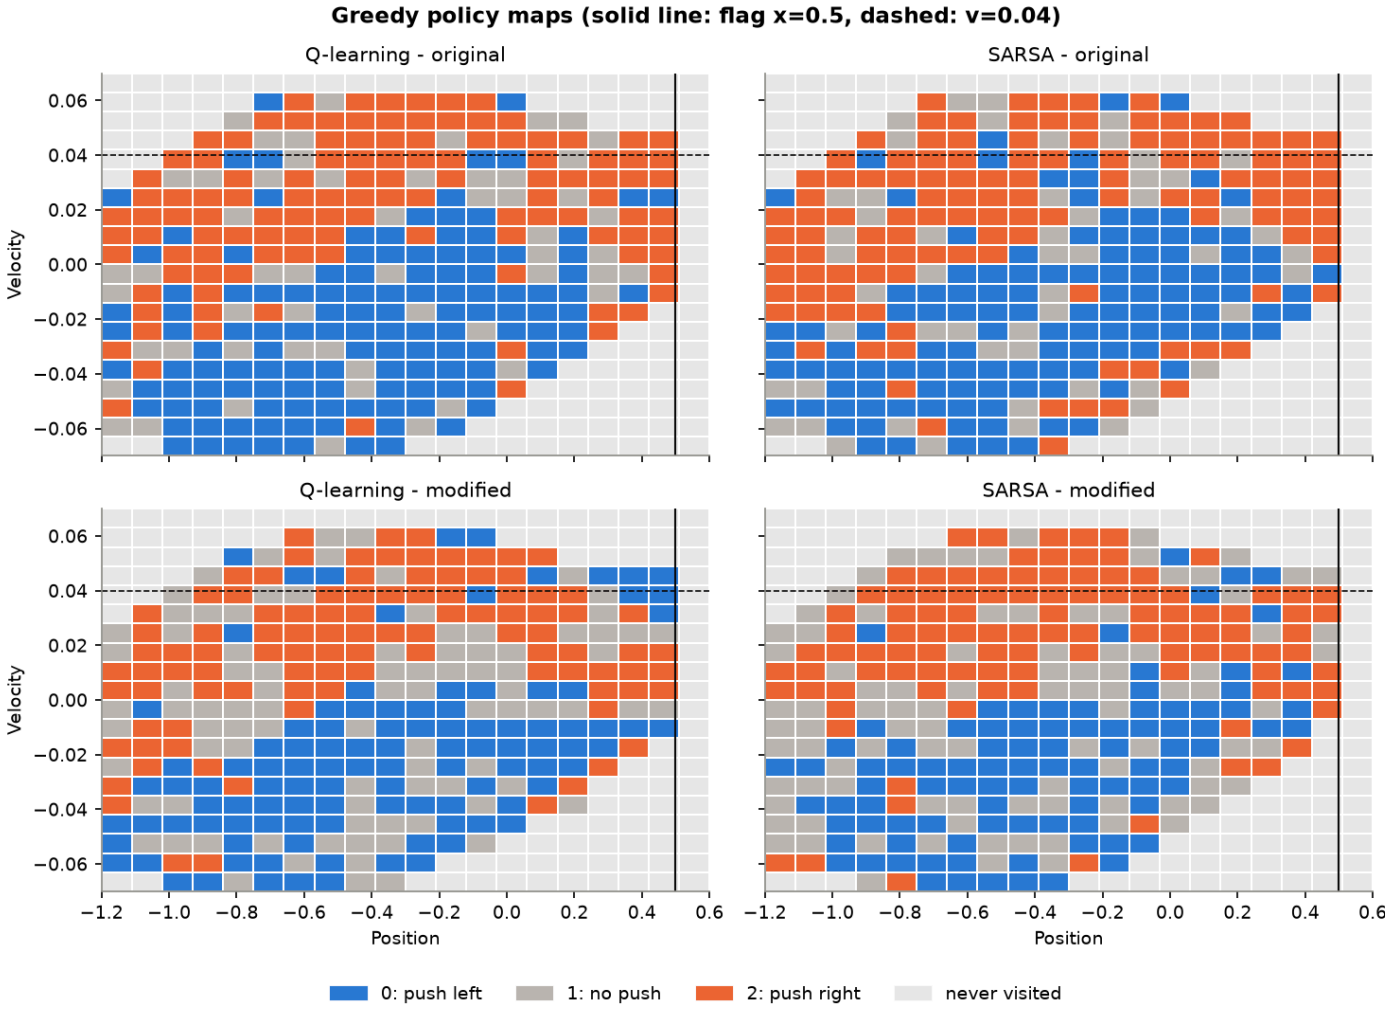

```
# Fig. d.4: number of push actions (0 or 2) selected per episode
plot_metric_panels(LOGS, "pushes", "Push actions (0 or 2) selected", "Push actions selected per episode",
"figures/fig4_pushes.png")
Image("figures/fig4_pushes.png", width=900)
```

Interpretation. At the start every agent selects about 134 pushes per 200-step episode. Under a near-random policy 2/3 of actions are pushes. In the **original** environment pushing is free, so the number of pushes stays high. Over the last 500 episodes it is 131.0 / 138.4 pushes per episode (Q-learning / SARSA), which is **84.0% / 86.1% of all steps**. In the **modified** environment the count falls steadily to 112.2 / 90.8, only **67.2% / 73.9% of steps**. Shorter episodes account for part of the drop, but the per-step push fraction also falls by about 14 percentage points. The energy penalty changes *how* the agents drive, not only how long. In the modified environment the two algorithms behave alike for most of training. SARSA ends with fewer pushes for this seed.

d.5 Greedy policy maps (position x velocity)

```
# Fig. d.5: greedy action per (position, velocity) cell for the four agents + action shares
DISC = UniformDiscretizer((CFG.n_pos_bins, CFG.n_vel_bins))
plot_policy_maps(EV["_maps"], DISC, "figures/fig5_policy_maps.png")
display(Image("figures/fig5_policy_maps.png", width=820))
pd.DataFrame(R["policy_maps"]).T.round(3)
```

	visited_cells	total_cells	frac_left	frac_none	frac_right
qlearning_original	299.0	400.0	0.431	0.184	0.385
sarsa_original	299.0	400.0	0.411	0.181	0.408
qlearning_modified	296.0	400.0	0.358	0.304	0.338
sarsa_modified	295.0	400.0	0.319	0.325	0.356

Interpretation. All four maps show the energy-pumping strategy that solves MountainCar. The agent pushes **left (blue) while the velocity is negative** and **right (orange) while it is positive**, so the blue/orange boundary runs roughly along v = 0. The light cells were never visited. They are physically unreachable combinations, such as high speed at the far left or large negative speed next to the flag. Out of 400 cells 299, 299, 296 and 295 were visited.

Original vs modified. (i) The modified maps contain many more **no-push (grey)** cells: 30% / 33% of visited cells, against 18% / 18% in the original environment. These cells sit mostly around low speed and in the middle of the swing, where coasting costs little momentum and saves 0.2 per step. (ii) Near the flag at high speed (top-right corner, above the dashed v = 0.04 line), the original agents keep pushing right. The modified agents coast or even push left to **brake**, which brings them in under the 0.04 limit.

Q-learning vs SARSA. Within one environment the maps share the same structure. They differ mainly in individual, rarely visited cells, where the values are still close together and the different TD targets tip the argmax one way or the other.

d.6 Greedy-policy evaluation: 100 test episodes, epsilon = 0, fixed seeds 10000-10099

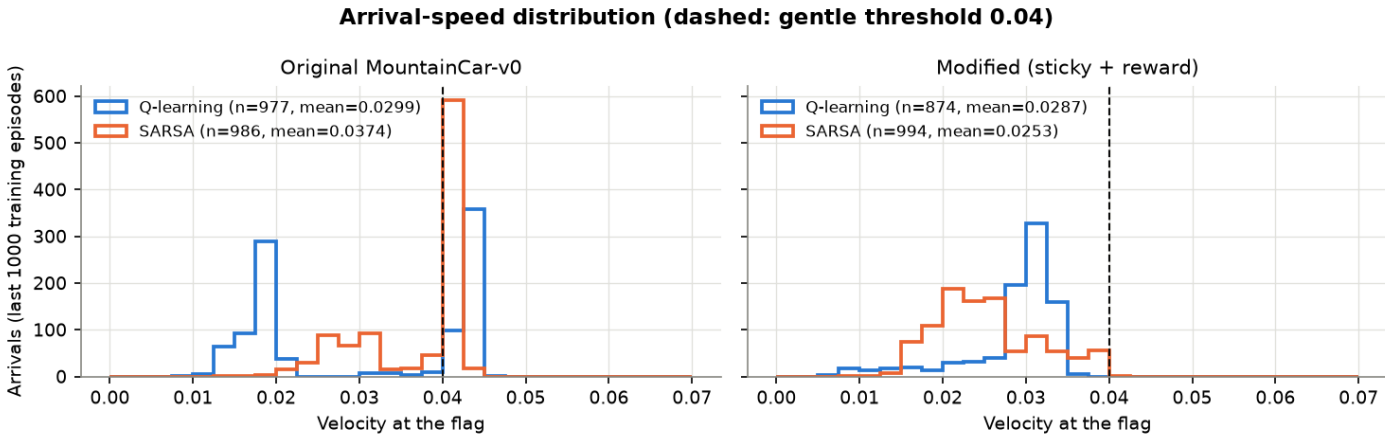

```
# One table with the four required metrics (+ pushes and arrival speed)
names = {"qlearning_original": "Q-learning - Original", "sarsa_original": "SARSA - Original",
         "qlearning_modified": "Q-learning - Modified", "sarsa_modified": "SARSA - Modified"}
tab = pd.DataFrame({names[k]: {"mean reward": v["mean_reward"], "std reward": v["std_reward"],
                               "success rate": v["success_rate"], "gentle-arrival rate": v["gentle_rate"],
                               "mean episode length": v["mean_length"], "mean pushes / episode": v["mean_pushes"],
                               "mean arrival velocity": v["mean_arrival_velocity"]}
                    for k, v in R["evaluation"].items()}).T
tab.round(3)
```

	mean reward	std reward	success rate	gentle-arrival rate	mean episode length	mean pushes / episode	mean arrival velocity
Q-learning - Original	-160.300	10.214	1.00	0.00	160.30	139.42	0.043
SARSA - Original	-160.750	15.299	1.00	0.00	160.75	142.60	0.042
Q-learning - Modified	-155.564	21.911	0.95	0.95	152.18	111.92	0.022
SARSA - Modified	-117.588	13.645	1.00	1.00	119.19	91.99	0.019

Interpretation. With epsilon = 0 on the same 100 test starts (and, for the modified environment, the same actuator-noise seeds), both **original-environment** agents reach the flag in 100% / 100% of episodes. Their gentle-arrival rate is only 0% / 0%, because they arrive at 0.043 / 0.042, near or just above the threshold. In the **modified environment** Q-learning reaches 95% success, 95% gentle and a mean reward of -155.6. SARSA reaches 100% success, 100% gentle and -117.6, with 119-step episodes and 92 pushes. In the modified environment every successful test episode is also a gentle arrival. For seed 84, SARSA is the better agent under sticky actuators. Section d.7 tests whether this holds across seeds.

d.7 Additional evidence: arrival speed, robustness across seeds, and transfer to the sticky environment

```
# Arrival-velocity histograms (last 1000 training episodes) for both environments
plot_arrival_speed(R["evaluation"], LOGS, "figures/fig6_arrival_speed.png")
Image("figures/fig6_arrival_speed.png", width=900)
```

```
# Every agent (including the two trained on the ORIGINAL env) tested in the MODIFIED env
cross = pd.DataFrame({names[k]: {m: v[m] for m in ["mean_reward", "success_rate", "gentle_rate", "mean_length",
"mean_pushes"]}
                      for k, v in R["cross_evaluation_modified_env"].items()}).T
cross.round(3)
```

	mean_reward	success_rate	gentle_rate	mean_length	mean_pushes
Q-learning - Original	-187.598	1.00	0.03	160.34	139.29
SARSA - Original	-186.748	0.96	0.29	163.93	143.09
Q-learning - Modified	-155.564	0.95	0.95	152.18	111.92
SARSA - Modified	-117.588	1.00	1.00	119.19	91.99

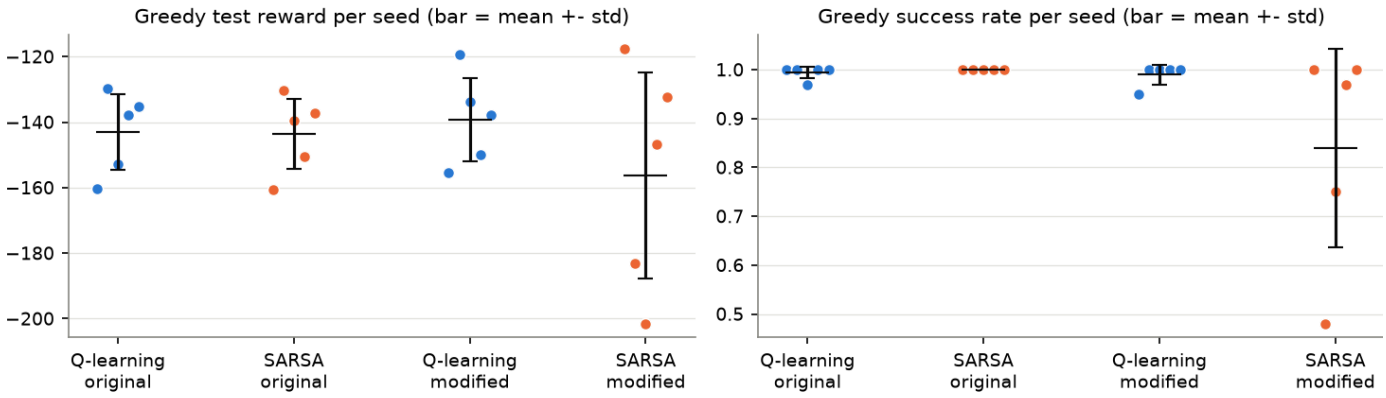

Transfer test. Every agent is evaluated in the **modified** environment. The two agents trained on the original environment still reach the flag (100% / 96%), so the sticky actuator alone does not break a pumping policy. However, they collect only -187.6 / -186.7, because they push on 87% of steps and arrive gently in only 3% / 29% of episodes. The agents trained in the modified environment score 32.0 (Q-learning) and 69.2 (SARSA) reward units more in the same environment. Training under the modified reward is what produces the gentle, energy-saving behaviour.

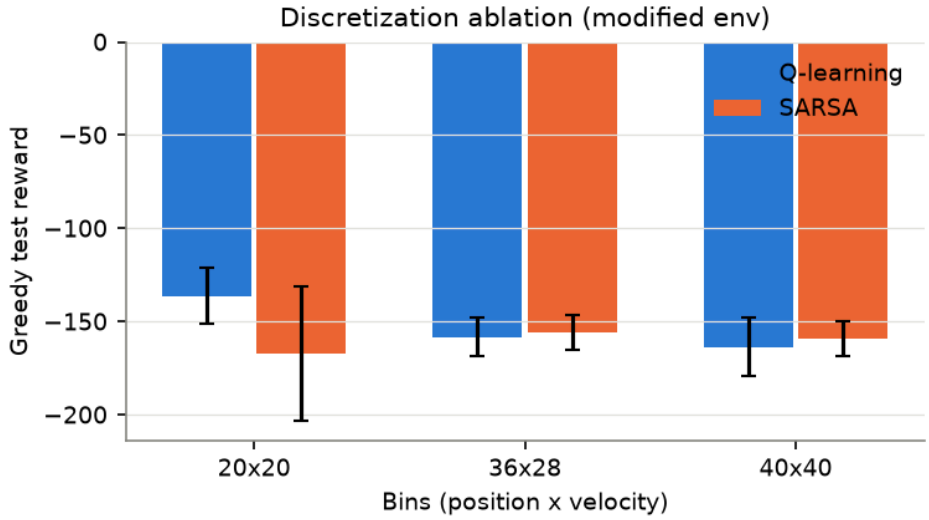

```

Robustness across seeds (84-88) and discretization. A single seed is not enough to rank the algorithms. Over five seeds:

Agent	greedy test reward	success	gentle	training reward (last 500, epsilon = 0.01)
Q-learning - original	-143.1 +- 11.5	99%	54%	-145.0 +- 10.6
SARSA - original	-143.7 +- 10.7	100%	60%	-150.1 +- 7.6
Q-learning - modified	-139.3 +- 12.7	99%	99%	-152.0 +- 13.8
SARSA - modified	-156.3 +- 31.4	84%	82%	-144.2 +- 17.0

In the **original** environment the two algorithms cannot be told apart. In the **modified** environment SARSA beats Q-learning on greedy test reward in **3 of 5** seeds, with a median of -146.7 against -137.9 for Q-learning. Its spread is much larger: on its worst seed the greedy SARSA policy succeeds in only 48% of test episodes. Q-learning's worst is 95%. The strong seed-84 SARSA result is therefore one good draw, not a typical outcome.

Discretization ablation (modified environment, seeds [84, 85, 86]): 20x20: Q -136.2, SARSA -167.4, 36x28: Q -158.2, SARSA -156.1, 40x40: Q -163.6, SARSA -159.2. Q-learning does best with 20x20. For SARSA, the finer grids give a smaller seed-to-seed spread (std 9.4 at 36x28 against 36.0 at 20x20).

(e1) Does the sticky actuator increase the difference between the value estimates of Q-learning and SARSA?

Yes, but only moderately, and mainly while the agents still explore. The value gap is V_Q-learning - V_SARSA, where V is the average of max_a Q(s,a) over the fixed validation set (Fig. d.2, right).

- **Seed 84.** Averaged over all 10000 episodes the gap is 5.70 (original) vs **6.94** (modified). In the first 20% of training (epsilon > 0.27) it is 15.53 vs **16.36**, and between 20% and 70% of training it is 4.78 vs **5.81**.
- **Five seeds.** The gap over the whole of training is 5.97 +- 0.38 (original) vs **7.06 +- 0.90** (modified). It is larger in the modified environment in **4 of 5** seeds, with a paired difference of 1.08 +- 1.10. In the high-exploration phase (first 20%) it is larger in **5 of 5** seeds (15.41 vs 16.63).
- **End of training.** At epsilon = 0.01 the gap is small and noisy in both environments (1.83 +- 1.97 vs 1.09 +- 1.99), so there is no difference left to detect.

Why. Q-learning's target max_a' Q(s',a') assumes that the best next action will be chosen **and executed**. SARSA's target Q(s',a') uses the action actually chosen, so its estimate already contains the cost of exploration. The sticky actuator adds a second, hidden source of noise. Every attempted switch, including exploratory ones, is delayed with probability 0.2, and the outcome of (s,a) depends on the unobserved a_prev. The values in each cell are therefore noisier. Taking a max over noisy estimates is biased upward (maximisation bias), while SARSA's sampled target is not, so the two estimates drift further apart. As epsilon reaches 0.01 the greedy and epsilon-greedy targets coincide and the gap closes in both environments.

Additional check (greedy Monte-Carlo returns from 200 validation states). We compare predicted values with actual returns, reported as bias = predicted - actual. In the original environment both algorithms show a positive bias: 9.7 for Q-learning and 12.2 for SARSA. This is the optimism left by state aggregation. In the modified environment, Q-learning still overestimates by 7.2, while SARSA's prediction is almost unbiased (-0.6). For seed 84, then, the on-policy estimate is the better-calibrated one under sticky actuators. This check uses one seed, so we treat it as supporting evidence only.

(e2) Why is the modified environment non-Markovian with respect to the observation, and how does this affect credit assignment?

An observation is Markov if P(o_t+1, r_t | o_t, a_t) does not depend on anything earlier. In the modified environment the executed action depends on **a_prev**, the action executed on the previous step. a_prev is not part of the observation (position, velocity). The true state is (x, v, a_prev), and the agent sees only (x, v). The same observation and the same selected action can therefore lead to different next-state distributions. We measured this directly (random policy, 65,867 steps where the agent selected *push right*):

hidden a_prev	P(push right is executed)	mean change in velocity
2 (right)	1.000	0.00100
0 (left)	0.798	0.00062

The table shows the agent is in a **POMDP**. The hidden variable is also produced by the agent's own past actions, so the effective transition probabilities of an observed state depend on the policy itself. This breaks the Markov assumption behind the convergence guarantees of tabular TD control.

Effects on credit assignment.

1. **Misattributed credit.** The energy penalty is charged on the *selected* action a_t, but the motion comes from a_exec, which after a stuck step is the *previous* action. The update of Q(s_t, a_t) is credited with the effect of a_t-1, and the effect of a_t only appears one or more steps later, where it is credited to whatever pair is updated then.
2. **Delayed and spread-out consequences.** A switch decision succeeds after a geometric number of attempts (mean 1/0.8 = 1.25 steps). Its consequence is spread over several transitions that one-step TD can only chain together by bootstrapping from aliased states.
3. **Noisier, aliased targets.** Every discretized cell mixes visits with different a_prev, so each target averages over the hidden variable. Learning slows down. The first success came at episode 1595 for Q-learning in the modified environment against 1089 in the original, and at 1213 vs 1125 for SARSA. Switching actions also becomes intrinsically risky, which favours policies that switch rarely.

(e3) Do the energy penalty and the gentle-arrival bonus encourage fewer pushes, or a slower, more controlled arrival?

Both: fewer pushes and a controlled arrival, with little change in trip length.

- **Fewer pushes (push-count plot, d.4).** Over the last 500 training episodes the agents push on 84.0% / 86.1% of steps in the original environment, against 67.2% / 73.9% in the modified one (Q-learning / SARSA). In the greedy test the counts fall from 139 / 143 to **112 / 92** pushes per episode. Over five seeds they fall from 124 / 127 to 101 / 105.
- **Policy maps (d.5).** The share of no-push cells rises from 18% / 18% to 30% / 33%. Near the flag at high speed the modified agents coast or brake instead of pushing right.
- **Controlled arrival (arrival-speed statistics, d.7).** The original agents arrive at a mean speed of 0.043 / 0.042 in the greedy test, with a gentle rate of 0% / 0%. The modified agents arrive at **0.022 / 0.019** with a gentle rate of **95% / 100%**. In the last 1,000 training episodes, 1 of the modified agents' arrivals exceeded 0.04, compared with 1068 for the original agents. Over five seeds the gentle rate is 54% / 60% (original) vs 99% / 82% (modified).
- **Trip length.** Greedy episodes in the modified environment last 152 / 119 steps, against 160 / 161 in the original. Over five seeds: 139 / 152 vs 143 / 144. The changes are within the seed-to-seed spread of about 25 steps (the largest std), so the agents do not systematically drive slower. The longer five-seed SARSA mean comes from its weak seeds 85, 86, whose greedy policies fail in part of the test episodes (truncated at 200 steps) or take long detours. Without them SARSA averages 133 steps.

The penalty of 0.2 is small next to the step cost of 1, and the +20 bonus is large. The best strategy is therefore still to reach the flag quickly, while dropping pushes that add little energy and shedding speed in the last few metres. The bonus is what controls arrival speed, since the original agents sit right at the 0.04 boundary by chance. The penalty is what removes unnecessary pushes.

(e4) Which algorithm performs better under sticky actuators, and is this consistent with on-policy vs off-policy theory?

- **Seed 84 (main study):** SARSA is better. Greedy test reward is -117.6 (SARSA) vs -155.6 (Q-learning), success 100% vs 95%, and last-500 training reward -121.1 vs -173.0.
- **Five seeds:** SARSA wins 3 of 5 seeds, with a median greedy reward of -146.7 vs -137.9. The mean, however, is -156.3 +- 31.4 for SARSA against -139.3 +- 12.7 for Q-learning, because SARSA occasionally produces a greedy policy that fails (worst seed: 48% success). Under the epsilon-greedy policy during training, the mean is -144.2 (SARSA) vs -152.0 (Q-learning).

Conclusion: it depends on which policy is measured. During training, while the agents follow their epsilon-greedy policy, SARSA is better on average (-144.2 vs -152.0). For the final greedy policy, Q-learning is better and more reliable (mean -139.3 vs -156.3, median -137.9 vs -146.7 for Q-learning vs SARSA). Neither algorithm wins on every seed.

Relation to theory. SARSA is on-policy. It learns the value of the policy it actually follows, including the cost of exploratory actions and, here, the cost of its own switches being delayed. So it should prefer "safer" behaviour, as in Sutton & Barto's cliff-walking example. Q-learning is off-policy. It learns the greedy policy's value as if every chosen action were executed, so its estimates are more optimistic, which is consistent with the value gap found in (e1). The theory therefore predicts a SARSA advantage *for the policy that is actually executed while exploring*, and a Q-learning advantage, if any, for the final greedy policy, because Q-learning learns the greedy policy's values directly. Our five-seed results match this pattern: SARSA is better under epsilon-greedy execution during training, and Q-learning has the better and more reliable greedy policy. Two caveats apply.

1. MountainCar has no catastrophic states, only extra -1 steps, and by the end of training epsilon = 0.01. The on-policy and off-policy targets then nearly coincide, so the theory itself predicts only a small difference, which is why the gaps between the algorithms are smaller than the seed-to-seed spread.
2. The sticky actuator makes the task non-Markov (e2). The convergence guarantees of both methods are lost, and seed-dependent aliasing effects dominate the remaining differences. This is why SARSA's advantage on some seeds does not hold across all of them.

(e5) One limitation and one improvement

Limitation. Our tabular agents observe only (position, velocity) on a 20x20 grid. The hidden actuator state a_prev, together with the coarse grid, aliases states that need different actions. As a result the learned greedy policy is fragile: SARSA's greedy test reward in the modified environment varies from -201.6 to -117.6 across five seeds, and the success rate swings during training (Fig. d.3). In addition, all conclusions rest on one hyper-parameter setting chosen on the modified environment, a constant alpha and only five seeds.

Improvement. Let the agent remember the information it is allowed to have: its own **previously selected action**. The environment does not expose the executed action, but the agent knows what it chose. Adding it as a third state dimension (a 20x20x3x3 Q-table) recovers most of the information about a_prev. Even under a uniform-random policy, which switches far more often than a trained agent, the previous selected action equals the hidden a_prev in 86.7% of steps. That would make the observation nearly Markov again. A complementary change is SARSA(lambda) / Q(lambda) with eligibility traces, which spreads credit over the few steps a delayed switch takes to act. A decaying learning rate and more seeds would reduce the variance seen above.

```

(f) Virtual-lab execution (screenshots with timestamps)

TODO before submission: run this notebook in the BITS virtual lab and create `VLAB_RUN.txt` (see README).

TODO before submission: add the timestamped virtual-lab screenshots to `screenshots/`.

Appendix A: Hyper-parameter pilot (`pilot_sweep.py`)

The pilot ran **before** the main study and used **different seeds** (master seeds 184, 284, 384 and evaluation seeds 50000+) from the final experiments (seed 84, evaluation seeds 10000+), so the reported test results were never used for tuning. It covered every combination of bins {20x20, 36x28, 40x40}, alpha {0.05, 0.1, 0.2}, epsilon-floor fraction {0.5, 0.7} and episodes {6000, 10000}, for both algorithms on the modified environment and 3 seeds each: 216 training runs. Below are the script and its top-10 configurations, ranked by mean greedy test reward.

```
# Print the full source of the hyper-parameter pilot script
print(open("pilot_sweep.py").read())
```

```
"""Hyper-parameter pilot (run BEFORE the main experiments).

Selects the discretization, learning rate, exploration-decay length and episode
budget used in the main study. To avoid tuning on the reported results, the pilot
uses different master seeds (184, 284, 384) and different evaluation seeds
(50000+ / 60000+) from the final experiments (seed 84, evaluation seeds 10000+).
Both algorithms are scored on the MODIFIED environment; the selection criterion
is the mean greedy-evaluation reward averaged over algorithms and seeds.

Usage:  python pilot_sweep.py          -> results/pilot.json

Appendix B: Command-line entry point (`run_experiments.py`)

The same experiments can be run without Jupyter. This script calls exactly the functions used above.

```
# Print the full source of the command-line entry point
print(open("run_experiments.py").read())
```

```
"""Run EVERY experiment of the assignment from the command line and save all numbers/figures.

The master notebook runs exactly the same functions (drl_sticky.experiments) cell by cell;
this script is the non-interactive equivalent.

Outputs
  results/results.json          all reported numbers
  results/logs/<run>.csv        per-episode log of each of the 4 main runs (every iteration)
  results/qtables/<run>.npy     final Q-tables
  results/validation_states.npy fixed validation set (sampled once, before training)
  figures/*.png                 all plots

Usage:  python run_experiments.py [--episodes N] [--seeds 84 85 86 87 88] [--quick]
"""

Appendix C: Complete per-episode training logs (every iteration)

One line per training episode for each of the four agents. **ep** = episode, **eps** = epsilon, **R** = episode reward, **len** = steps, **S** = reached flag, **G** = gentle arrival, **P** = push actions selected, **V** = average max_a Q on the validation set, **x** = sticky replacements (modified environment only). The same data is saved as CSV in `results/logs/`.
